1 Entering and Importing Data

1.1 Use R to do the following exercises.

1.1.1 Enter the following into a data structure with the name `color`:

- purple
- yellow
- red
- brown
- green
- purple
- red
- purple

```
color <- c("purple", "yellow", "red", "brown", "green",  
           "purple", "red", "purple")
```

1.1.2 Display the 2nd element of `color`.

```
color[2]  
  
## [1] "yellow"
```

1.1.3 Enter the following into a data structure with the name `weight`:

- 23
- 21
- 18
- 26
- 25
- 22
- 26
- 19

```
weight <- c(23, 21, 18, 26, 25, 22, 26, 19)
```

1.1.4 What are the lengths of `color` and `weight`? Use a function to answer this.

```
length(color)

## [1] 8

length(weight)

## [1] 8
```

1.1.5 Join `color` and `weight` together using `cbind()` and assign it to the object `micecbind`.

```
micecbind <- cbind(color = color, weight = weight)
```

1.1.6 What is the data structure of `micecbind`? What are the dimensions? Are the weights still numbers (`num`) or were they converted to characters (`chr`)?

```
micecbind

##      color  weight
## [1,] "purple" "23"
## [2,] "yellow" "21"
## [3,] "red"    "18"
## [4,] "brown"  "26"
## [5,] "green"  "25"
## [6,] "purple" "22"
## [7,] "red"    "26"
## [8,] "purple" "19"

str(micecbind)

## chr [1:8, 1:2] "purple" "yellow" "red" "brown" "green" "purple" "red" ...
## - attr(*, "dimnames")=List of 2
## ..$ : NULL
## ..$ : chr [1:2] "color" "weight"

dim(micecbind)

## [1] 8 2
```

Using `str` we see that `micecbind` is a matrix with dimensions 8 x 2 and the weights were converted to characters, which we don't want! The function `dim` can also be used to extract only the dimensions.

- 1.1.7 Now join `color` and `weight` together using `data.frame()` with argument `stringsAsFactors = FALSE` and assign it to the object `micedf`.

```
micedf <- data.frame(color = color, weight = weight, stringsAsFactors = FALSE)
```

- 1.1.8 What is the data structure of `micedf`? What are the dimensions? Are the weights still numbers (`num`) or were they converted to characters (`chr`)?

```
micedf

##      color weight
## 1 purple      23
## 2 yellow      21
## 3   red       18
## 4 brown       26
## 5 green       25
## 6 purple      22
## 7   red       26
## 8 purple      19

str(micedf)

## 'data.frame': 8 obs. of  2 variables:
##  $ color : chr  "purple" "yellow" "red" "brown" ...
##  $ weight: num  23 21 18 26 25 22 26 19

dim(micedf)

## [1] 8 2
```

Using `str` we see that `micedf` is a data frame with dimensions 8 x 2, with variable `color` a character vector and `weight` a numeric vector. The function `dim` can also be used to extract only the dimensions. Thankfully the weights were not converted to characters!

1.1.9 Display only the 3rd row of `micedf`.

```
micedf[3, ]  
  
##   color weight  
## 3   red     18
```

1.1.10 Display only the 2nd column (“weight”) of `micedf`. Do so in two different ways.

Any two of the following are satisfactory:

```
micedf[, 2]  
micedf[, -1]  
micedf[, "weight"]  
micedf[[2]]  
micedf$weight  
micedf["weight"]
```

1.1.11 Display the dimensions of `micedf`.

```
dim(micedf)  
  
## [1] 8 2
```

1.1.12 Assign the following strings to the row names of `micedf`:

- mouse1
- mouse2
- mouse3
- mouse4
- mouse5
- mouse6
- mouse7
- mouse8

Hint: try using `paste`.

```
row.names(micedf) <- paste("mouse", 1:8, sep = "")
```

1.1.13 Create a list containing three elements and assign it to `mylist`:

- `micedf`
- A data frame of `micedf` with a new column called `double` that is 2 times the second column of `micedf` (`weight`). (Did you get an error? Make sure that the second column is numeric and if it isn't, change it!)
- The names of `micedf`.

```
mylist <- list(micedf,  
              data.frame(micedf, double = 2 * micedf$weight),  
              names(micedf))
```

1.1.14 Assign these names to `mylist`: `first`, `second`, `third`.

```
names(mylist) <- c("first", "second", "third")
```

1.1.15 Display `mylist`. What does it look like?

```
mylist  
  
## $first  
##      color weight  
## mouse1 purple    23  
## mouse2 yellow    21  
## mouse3   red     18  
## mouse4  brown    26  
## mouse5  green    25  
## mouse6 purple    22  
## mouse7   red     26  
## mouse8 purple    19  
##  
## $second  
##      color weight double  
## mouse1 purple    23     46  
## mouse2 yellow    21     42  
## mouse3   red     18     36  
## mouse4  brown    26     52
```

```
## mouse5 green 25 50
## mouse6 purple 22 44
## mouse7 red 26 52
## mouse8 purple 19 38
##
## $third
## [1] "color" "weight"
```

A list with three items with the given names preceded by \$. The first two entries are data frames and have row names, but the third does not (it is a character vector).

1.1.16 Display only the second element of `mylist`. Do so in two different ways.

Any two of the following are satisfactory:

```
mylist[[2]] ## extract
mylist$second ## extract
mylist[2] ## subset
mylist[-c(1, 3)] ## subset
mylist["second"] ## subset
```

1.1.17 Write `micedf` to a file called “micedf1.csv” in the course directory.

```
write.csv(micedf, "micedf1.csv")
```

1.1.18 Open “micedf1.csv” in Excel and describe what you see. Repeat the step above but do not include row names and call the file “micedf2.csv”. How is the output different from “micedf1.csv”?

The file “micedf1.csv” looks exactly like the data frame when displayed in R.

```
write.csv(micedf, "micedf2.csv", row.names = FALSE)
```

The file “micedf2.csv” looks just like the data frame above, but it is missing the row names.

1.1.19 Now read in “micedf1.csv” and “micedf2.csv” into R in two new objects (`newmice1` and `newmice2`, respectively). Describe any differences between the two objects. What are the dimensions of each object?

```

newmice1 <- read.csv("micedf1.csv")
newmice2 <- read.csv("micedf2.csv")
str(newmice1)

## 'data.frame': 8 obs. of  3 variables:
##  $ X      : Factor w/ 8 levels "mouse1","mouse2",...: 1 2 3 4 5 6 7 8
##  $ color   : Factor w/ 5 levels "brown","green",...: 3 5 4 1 2 3 4 3
##  $ weight: int   23 21 18 26 25 22 26 19

str(newmice2)

## 'data.frame': 8 obs. of  2 variables:
##  $ color   : Factor w/ 5 levels "brown","green",...: 3 5 4 1 2 3 4 3
##  $ weight: int   23 21 18 26 25 22 26 19

newmice1

##           X  color weight
## 1 mouse1 purple      23
## 2 mouse2 yellow      21
## 3 mouse3   red       18
## 4 mouse4 brown       26
## 5 mouse5 green       25
## 6 mouse6 purple      22
## 7 mouse7   red       26
## 8 mouse8 purple      19

newmice2

##      color weight
## 1 purple      23
## 2 yellow      21
## 3   red       18
## 4 brown       26
## 5 green       25
## 6 purple      22
## 7   red       26
## 8 purple      19

```

The first file was written with row names, but when we read it into R, the row

names are now just a column in the data frame. Because there was an empty cell in the space where a column name should have been, R names it **X**. The second file had no row names, and, just like the first file, is given the default row names of 1 to the number of rows. The dimensions are 8 x 3 and 8 x 2, respectively (seen in the output of the **str** call).

- 1.1.20 Read in “micedf1.csv” into R (assign to object **newmice3**). Use the argument **row.names** to indicate that the first column should be row names and do not allow strings to be turned into factors. Display the object and the structure of the object and describe how it is different from **newmice1** and **micedf**. What are the dimensions of **newmice3**?

```
newmice3 <- read.csv(paste(mydir, "micedf1.csv", sep="/"),
                     row.names = 1, stringsAsFactors = F)
```

```
str(newmice3)

## 'data.frame': 8 obs. of 2 variables:
## $ color : chr  "purple" "yellow" "red" "brown" ...
## $ weight: int  23 21 18 26 25 22 26 19

newmice3

##           color weight
## mouse1 purple      23
## mouse2 yellow      21
## mouse3   red       18
## mouse4  brown      26
## mouse5  green      25
## mouse6 purple      22
## mouse7   red       26
## mouse8 purple      19
```

The new object **newmice3** now has row names where in **newmice1** they were treated as a variable in the data frame. The **color** variable was not converted to a factor, unlike in **newmice1**. The new object **micedf** is now (nearly) identical to the original **micedf**. It has the same row names and dimensions as **micedf**. The only difference is the class of **weight** is an integer instead of just “numeric” (more specific). The dimensions are 8 x 2.

1.2 Use R to do the following exercises on the Puromycin data.

1.2.1 Load the Puromycin data using the `data()` function.

```
data(Puromycin)
```

1.2.2 What is the data structure of Puromycin? What are the dimensions? Do not just display the data (this is not convenient for large datasets).

```
str(Puromycin)

## 'data.frame': 23 obs. of 3 variables:
## $ conc : num 0.02 0.02 0.06 0.06 0.11 0.11 0.22 0.22 0.56 0.56 ...
## $ rate : num 76 47 97 107 123 139 159 152 191 201 ...
## $ state: Factor w/ 2 levels "treated","untreated": 1 1 1 1 1 1 1 1 1 1 ...
## - attr(*, "reference")= chr "A1.3, p. 269"
```

Using `str` we see that `Puromycin` is a data frame with dimensions 23 x 3, with variables `conc` and `rate` numeric vectors and `state` a factor with 2 levels.

1.2.3 What are the names of Puromycin? Use a function other than `str`.

```
names(Puromycin)

## [1] "conc" "rate" "state"
```

1.2.4 What are the levels of the `state` variable? Use a function other than `str`.

```
levels(Puromycin$state)

## [1] "treated" "untreated"
```

1.2.5 Display the rate for all concentrations less than 0.10 in the treated group.

```
Puromycin[Puromycin$conc < .10 & Puromycin$state == "treated", "rate"]

## [1] 76 47 97 107

## or
Puromycin$rate[Puromycin$conc < .10 & Puromycin$state == "treated"]
```

```
## [1] 76 47 97 107

## or
Puromycin[["rate"]][Puromycin$conc < .10 & Puromycin$state == "treated"]

## [1] 76 47 97 107
```

1.2.6 What are the row indices for the concentrations of 0.22?

```
which(Puromycin$conc == 0.22)

## [1] 7 8 19 20
```

If you want to save your work: save your R session and/or source code!
