## Basic Course on R: Programming Structures 2 Practical Answers

Elizabeth Ribble\*

28 Oct - 1 Nov 2019

## Contents

1	Part A: Scope	2
<b>2</b>	Part B: if() Statements, warning(), and stop()	4

<sup>\*</sup>emcclel 3@msuden ver.edu

## 1 Part A: Scope

1. For each of the following sets of commands, give the value that will be returned by the last command. Try to answer without using R.

```
a) w <- 5
    f <- function(y) {
        return(w + y)
    }
    f(y = 2)
## [1] 7</pre>
```

This will return 7 because w is 5 and we are evaluating the function at y = 2.

```
b) w <- 5
    f <- function(y) {
        w <- 4
        return(w + y)
    }
    f(y = 2)
## [1] 6</pre>
```

This will return 6 because w is reassigned as 4 inside the function and we are evaluating the function at y = 2.

2. Among the variables w, d, and y, which are global to f() and which are local?

```
w <- 2
f <- function(y) {
    h <- function() {
        d <- 3
        return(w + y)
        }
    return(d * h())
}</pre>
```

The object w is global to f() while d and y are local to f().

- 3. Do the following in R.
  - a) Try:

```
myFun1 <- function() {
    a <- 2
    b <- 3
    myFun2(3)
}
myFun2 <- function(y) {
    return(y + a + b)
}
myFun1()
## Error in myFun2(3): object 'a' not found</pre>
```

What happens?

We get an error message because a and b are local to myFun1 so the function myFun2 can't find them in the global environment.

b) Now try:

```
a <- 1
b <- 2
myFun1()
## [1] 6
```

What happens?

We get get the value 6 because the values **a** and **b** are global so **myFun2** can find them and use them in its commands.

4. What value for  $\mathbf{w}$  will be printed in the last line below? Try to answer without using R.

```
w <- 1
f <- function(y) {
    g <- function() {
        w <<- 3
        return(2)
    }
    return(g())
}</pre>
```

```
## [1] 2

W

## [1] 3
```

We get the value 3 because the superassign operator overwrote the original assignment of  ${\tt w}$ .

5. What value for  $\mathbf{w}$  will be printed in the last line below? Try to answer without using R.

```
w <- 1
f <- function(y) {
    w <- 2
    g <- function() {
        w <<- 3
        return(2)
        }
    return (g())
}

## [1] 2</pre>

## [1] 1
```

We get the value 1 because the superassign operator only overwrote the assignment of  ${\tt w}$  within the  ${\tt f}$  () function.

## 2 Part B: if() Statements, warning(), and stop()

The functions warning() and stop() are used to print a warning message and to stop the execution of the function call and print an error message. For example:

```
noNegMean <- function(x) {
  if(all(x < 0)) {
    stop("All values in x are negative")</pre>
```

```
}
if(any(x < 0)) {
    x[x < 0] <- 0
    warning("Negative values in x replaced by zero")
    }
return(mean(x))
}</pre>
```

1. The file **nonegmean.txt** contains the above code; source it into R and then pass **noNegMean()** a vector containing some negative and some positive values. What happens?

```
source("nonegmean.txt")
noNegMean(c(-1,0,1))

## Warning in noNegMean(c(-1, 0, 1)): Negative values in x replaced
by zero

## [1] 0.3333333
```

We get the warning message and it returned 0.3333, which is the average of 0, 0, 1.

2. What happens when you pass noNegMean() a vector containing all negative values?

```
source("nonegmean.txt")
#noNegMean(c(-1,-1,-1)) # not run; error message
```

We get the error message and nothing is returned.

3. Write a function ratio() that takes two arguments, x and y, and attempts to compute the ratio x/y. If both x == 0 & y == 0, the function should stop and print an error message about dividing 0 by 0. If y == 0 (but not x), the function should print a warning message about dividing by 0, and then return x/y (which will be Inf). In all other cases, it should return x/y.

Test your ratio() function first using two nonzero values for x and y, then using a nonzero x but y = 0, and finally using x = 0 and y = 0.

```
ratio <- function(x,y) {
    if(x == 0 & y == 0) {
        stop("Cannot divide zero by zero.")
    }
    if(y == 0) {
        warning("Cannot divide by zero.")
    }
    ratio <- x/y
    return(ratio)
}

ratio(2,3)

## [1] 0.66666667

ratio(0,0)

## Error in ratio(0, 0): Cannot divide zero by zero.

ratio(1,0)

## Warning in ratio(1, 0): Cannot divide by zero.

## [1] Inf</pre>
```
